

Chapter 1

Exercises

Exercise 1

Calculate the average number of particles in an electromagnetic shower initiated by a 50 GeV photon, after 10, 13 and 20 cm of crossed iron.

Hint: search for the radiation length of the iron on the PDG.

Searching on Particle Data Group^a, we find for e^- :

$$X_0^{\text{Fe}} = 1.757 \text{ cm} \quad (1.1)$$

$$E_C^{\text{Fe}} = 21.68 \text{ MeV} \quad (1.2)$$

So, until the energy of the product particles is lower than the critical energy E_C , we have:

$$N(x) = 2^{\frac{x}{X_0^{\text{Fe}}}} \quad (1.3)$$

We find these values:

$$N(x = 10 \text{ cm}) \approx 52 \quad (1.4)$$

$$N(x = 13 \text{ cm}) \approx 169 \quad (1.5)$$

$$N(x = 20 \text{ cm}) \approx N(x \approx 19.6 \text{ cm}) \approx 2306 \quad (1.6)$$

We note that for $x = 20 \text{ cm}$, the critical energy has already been reached at $x \approx 19.6 \text{ cm}$, so the number of product particles has to be computed at this distance with Eq. 1.3.

Exercise 2

A muon of 100 GeV energy crosses without being absorbed a detector whose mass is mainly due to the hadronic calorimeter and to the muon detector. The thickness of the crossed material can be considered as a layer of 3 m of iron. Determine:

- What is the dominant energy loss process.
- The average loss of the muon inside the detector.

Hint: look at the energy loss picture of muons.
